## Output Discussion

### *Step1: Output without Pthreads synchronization*

In step1, no mechanism has been used for synchronization, thus, there is no idea about the final see. For example, in the case of 4 threads, the final see is different for one thread to another. Thread1 see final value 39 whereas thread3 see final value 52. Even if I repeatedly run the program multiple times, value of the final see always changed but never synchronized. Similar behavior has been observed for different thread sizes e.g. 2, 3, 4 up to 200. However, the program with a single thread observed as synchronization which is obvious. The output of a 4 thread run is depicted in the figure below.

ive a grade of zero.

### Step2: Output with Pthreads synchronization

In step2, a locking mechanism has been introduced for synchronization, thus, the final see for all threads is always same. For example, in the case of 4 threads, the final see is 80 for all threads. More preciously, Thread1 see final value 80 and thread3 see final value 80 too. Even if I repeatedly run the program multiple times, value of the final see always same which is a clear indication of synchronization. Similar behavior has been observed for different thread sizes e.g. 2, 3, 4 up to 200. Similarly, the program with a single thread observed as synchronization which is obvious. The output of a 4 thread run is depicted in the figure below.

A terminal window titled "Terminal" with a menu bar (File, Edit, View, Search, Terminal, Help) and a status bar (6:33 PM). The prompt is "mmamu009@pg6-142-d606:~/FIU/Fall19/OS/Project1\$". The command executed is "./projec". The output shows four threads (thread0, thread1, thread2, thread3) each printing a sequence of values from 0 to 54. The values are printed in a sequential order across the threads, indicating synchronization. The output is as follows:

```
t1 4
***thread0 sees value 0
***thread0 sees value 1
***thread0 sees value 2
***thread0 sees value 3
***thread0 sees value 4
***thread0 sees value 5
***thread0 sees value 6
***thread0 sees value 7
***thread0 sees value 8
***thread0 sees value 9
***thread0 sees value 10
***thread0 sees value 11
***thread0 sees value 12
***thread0 sees value 13
***thread0 sees value 14
***thread0 sees value 15
***thread0 sees value 16
***thread0 sees value 17
***thread0 sees value 18
***thread0 sees value 19
***thread1 sees value 20
***thread1 sees value 21
***thread1 sees value 22
***thread1 sees value 23
***thread1 sees value 24
***thread1 sees value 25
***thread1 sees value 26
***thread1 sees value 27
***thread1 sees value 28
***thread1 sees value 29
***thread1 sees value 30
***thread1 sees value 31
***thread1 sees value 32
***thread1 sees value 33
***thread1 sees value 34
***thread1 sees value 35
***thread1 sees value 36
***thread1 sees value 37
***thread1 sees value 38
***thread1 sees value 39
***thread2 sees value 40
***thread2 sees value 41
***thread2 sees value 42
***thread2 sees value 43
***thread2 sees value 44
***thread2 sees value 45
***thread2 sees value 46
***thread2 sees value 47
***thread2 sees value 48
***thread2 sees value 49
***thread2 sees value 50
***thread2 sees value 51
***thread2 sees value 52
***thread2 sees value 53
***thread2 sees value 54
```

```
***thread2 sees value 51
***thread2 sees value 52
***thread2 sees value 53
***thread2 sees value 54
***thread2 sees value 55
***thread2 sees value 56
***thread2 sees value 57
***thread2 sees value 58
***thread2 sees value 59
***thread3 sees value 60
***thread3 sees value 61
***thread3 sees value 62

***thread2 sees final value 80
***thread1 sees final value 80
***thread0 sees final value 80
***thread3 sees final value 80
mmanu009@pg6-142-d606:~/FIU/Fall19/OS/Project1$
```

## Reasons for the difference

In step1

- The shared variable was unlocked, thus any thread can access/execute the critical section aka shared variable before first thread finishes.
- Thread barrier has not used, thus none of the threads are waiting until previous threads finish.

Therefore, the final sees are not the same for all the threads that result in unsynchronized output because no synchronization technique is applied in step1. The figure of Pthreads with synchronization shows the inconsistency between outputs.

In step2

- The shared variable was locked using mutex and release after used, thus no thread can access the shared variable until the previous thread completed its use.
- Thread barrier has used, thus all threads are waiting to go together that results in the same output (final sees) for all the threads.

Therefore, the final sees are the same for all the threads and output is well synchronized because one of the synchronization techniques e.g. mutex is used in step2. The figure of Pthreads without synchronization shows the consistency between threads.

## Program Design

To overcome the race condition, I have used a popular synchronization technique called **Mutexes**. It protects the critical region from unexpected use. I have organized my program as follows.

- I have initialized, created, and joined multiple threads using **Pthread[1]** in the *main* function.
- **Mutex**, a locking mechanism is initialized in the main function.
- I set the mutex before using the shared variable and release it after using it in the *SimpleThread* function where the shared variable is increasing.
- I have also used **Pthread** barrier before assigning the final value to the shared variable at the end of *SimpleThread* function to allow all the threads to wait until the finish.
- Finally, *pthread\_mutex\_destroy* has been used at the end of the main function to destroy used mutexes.
- Moreover, I have checked the number of command-line parameters at the beginning of the main function. Also, I make sure the user can only pass a positive number as an argument which is the number of threads.

## **Conclusion**

I have developed my code in locking fashion using Mutex to ensures synchronization among the threads while working on the shared variable.
